

Montreal, Quebec, Canada, November 3rd, 2025 - A conference was held in Montreal, Quebec, Canada, on November 3rd, 2025. The conference was organized by the Canadian Association of Neuroscience and Psychology (CANP) and the Canadian Society for Neuroscience (CSN). The purpose of the conference was to bring together researchers, scientists, and professionals from various fields of neuroscience and psychology to share their latest findings and discuss future research directions. The conference featured several keynote speeches, panel discussions, and poster presentations. The attendees included students, postdoctoral fellows, and faculty members from universities and research institutions across Canada and abroad. The conference was a success and provided a valuable opportunity for networking and collaboration among the scientific community.

convolutional neural network

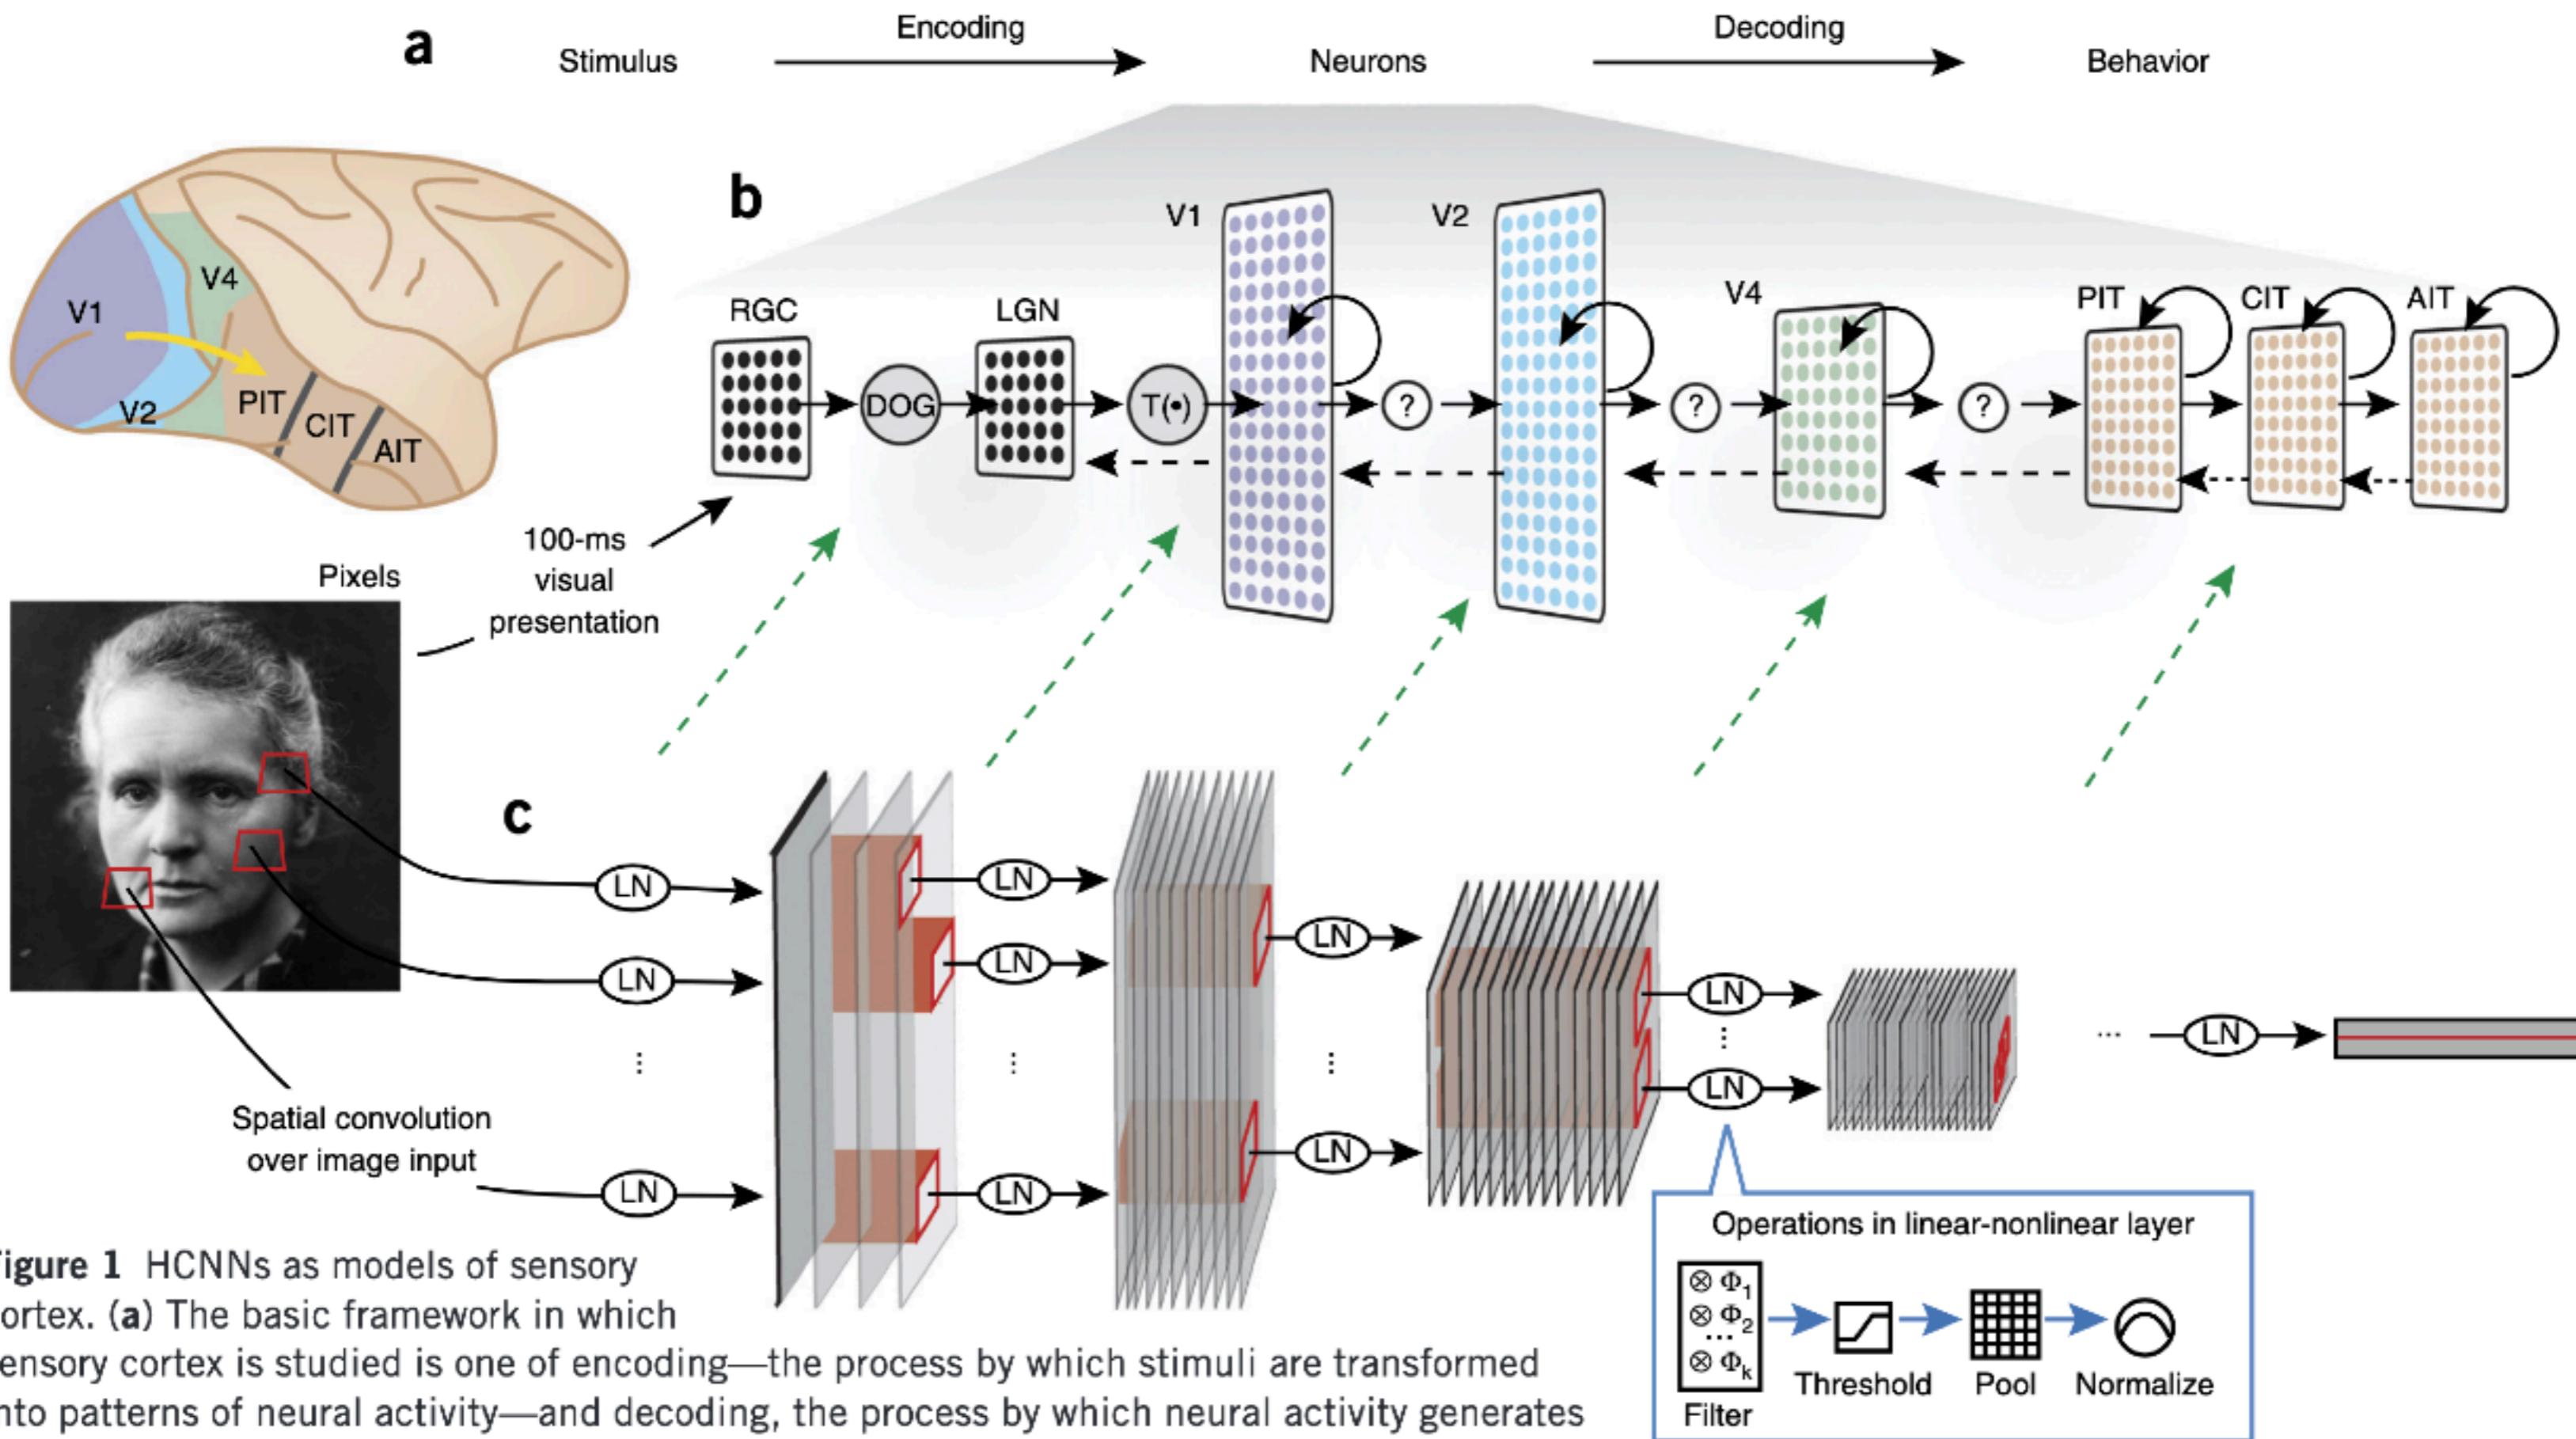

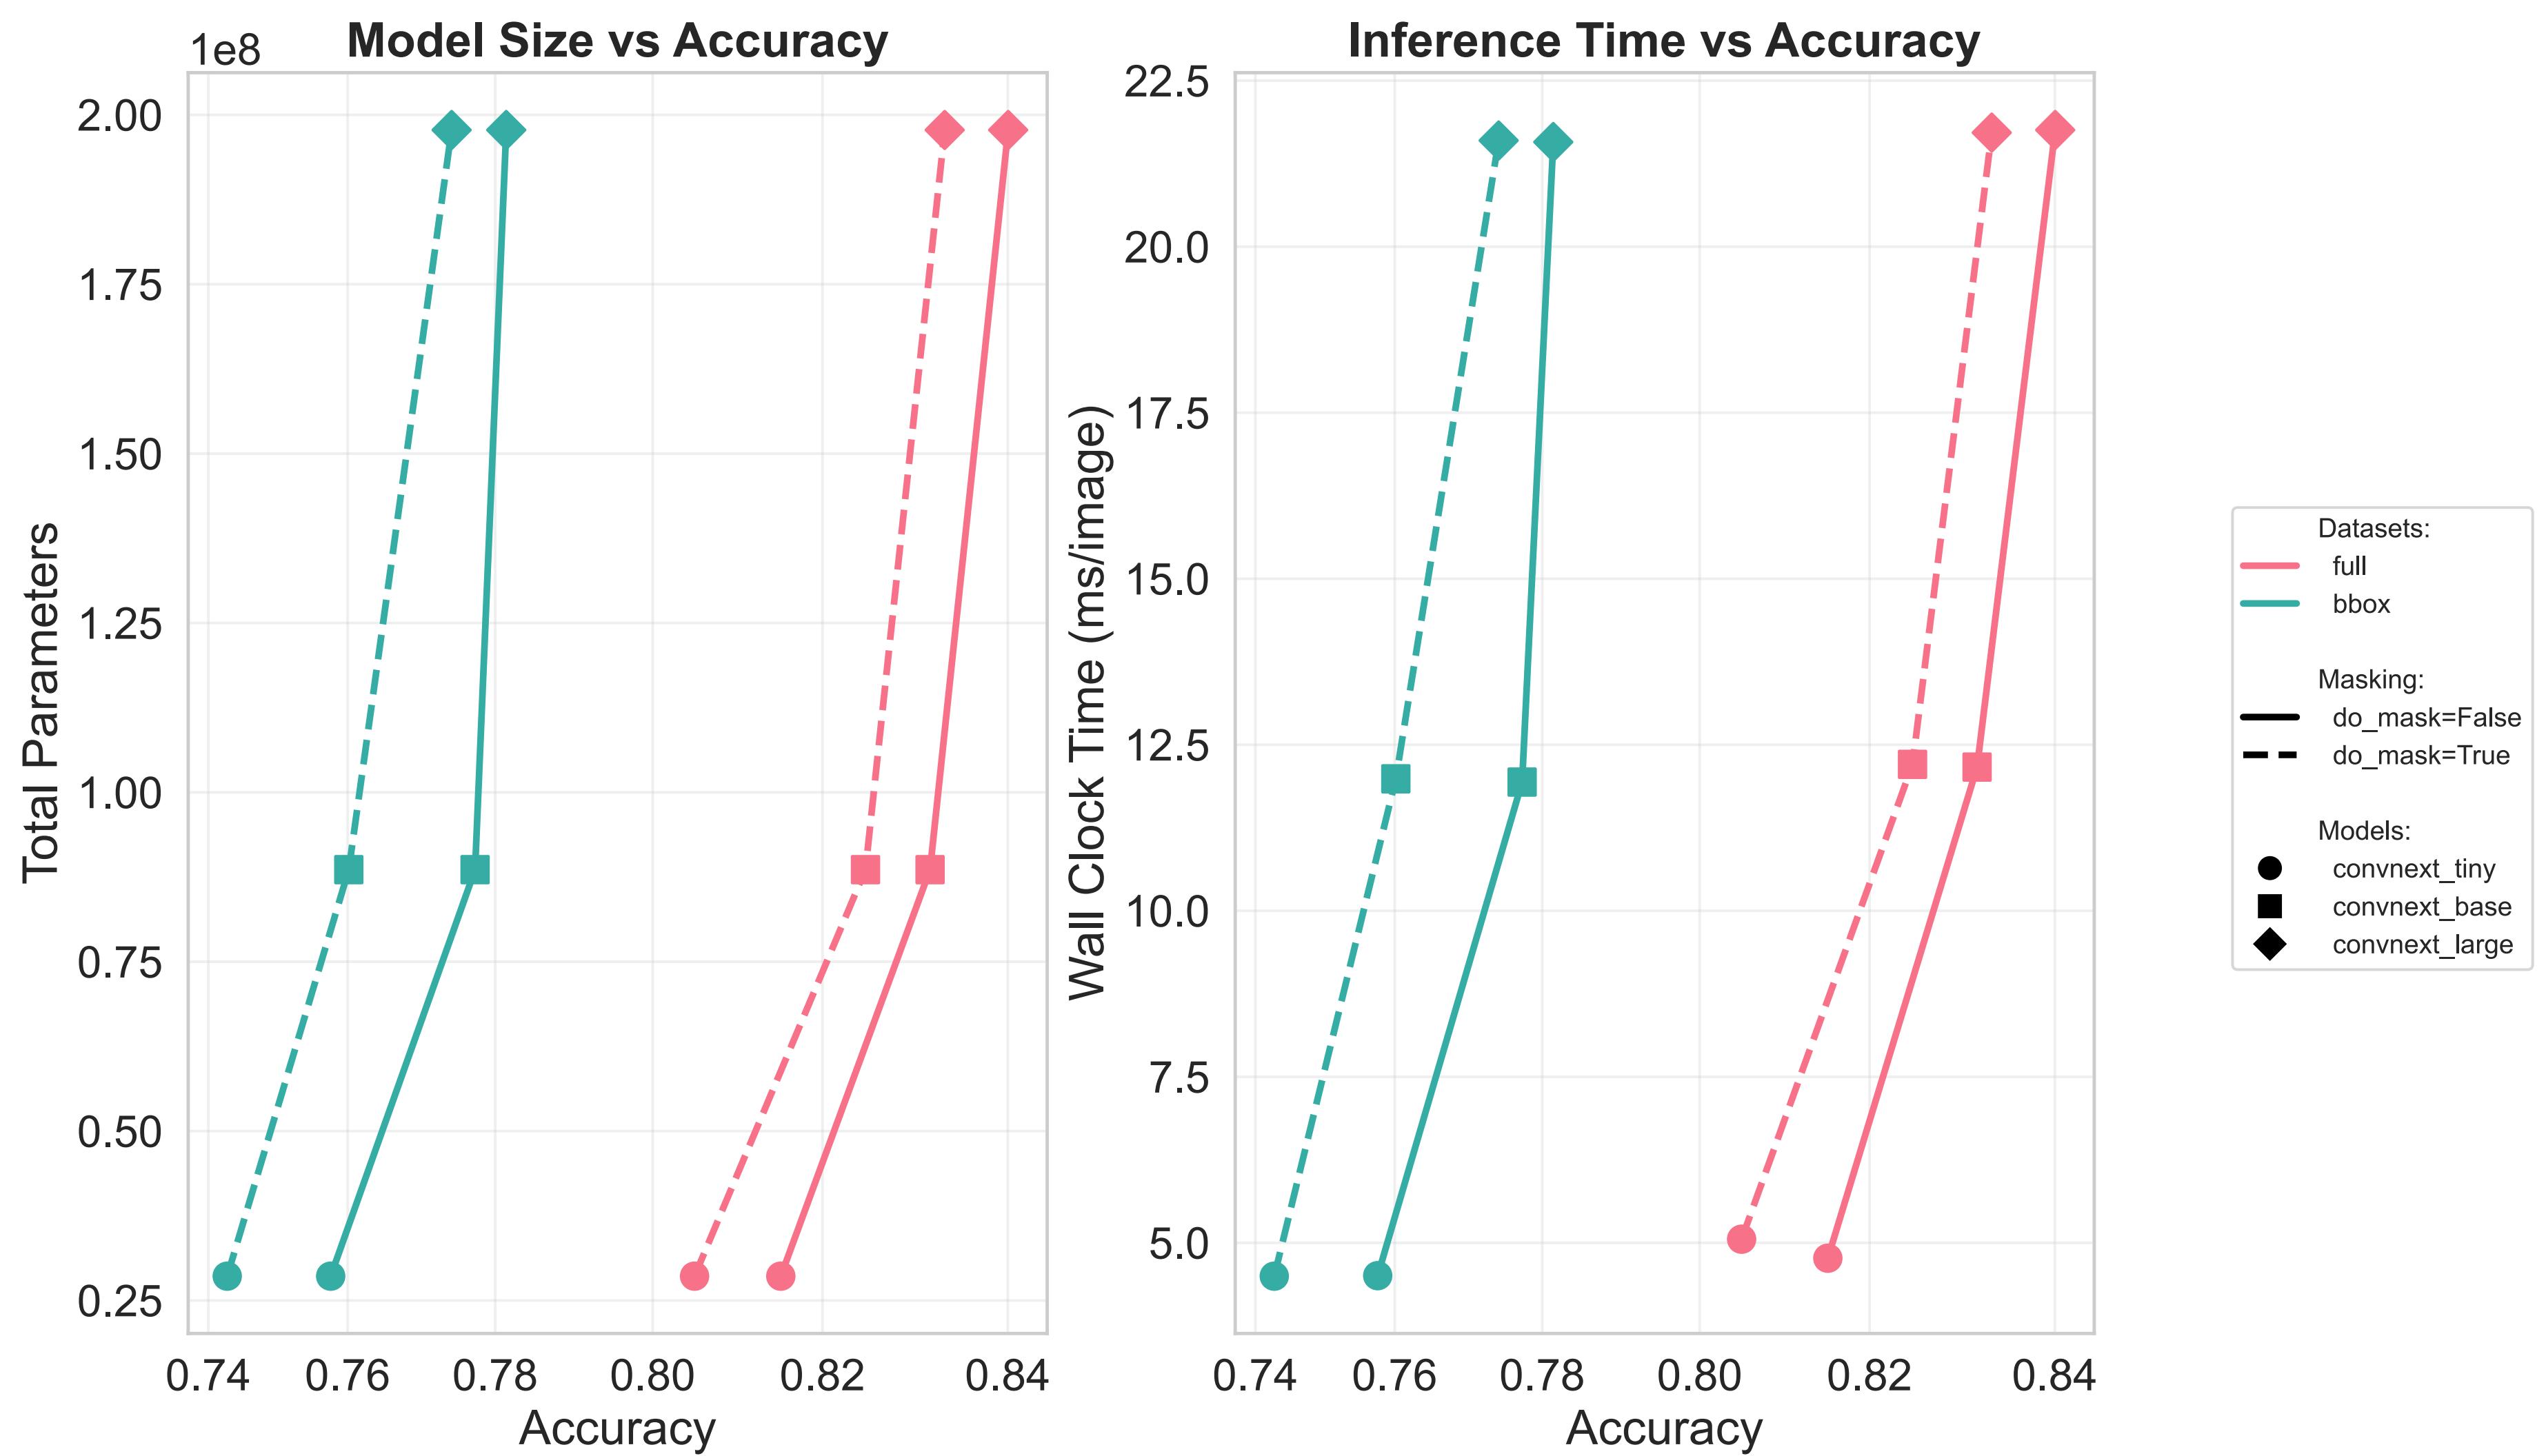

Figure 1 HCNNs as models of sensory cortex. **(a)** The basic framework in which sensory cortex is studied is one of encoding—the process by which stimuli are transformed into patterns of neural activity—and decoding, the process by which neural activity generates behavior. HCNNs have been used to make models of the encoding step; that is, they describe the mapping of stimuli to neural responses as measured in brain. **(b)** The ventral visual pathway is the most comprehensively studied sensory cascade.

Abstract

Deep convolutional networks have become a popular tool for image generation and restoration. Generally, their excellent performance is imputed to their ability to learn realistic image priors from a large number of example images. In this paper, we show that, on the contrary, the structure of a generator network is sufficient to capture a great deal of low-level image statistics prior to any learning. In order to do so, we show that a randomly-initialized neural network can be used as a handcrafted prior with excellent results in standard inverse problems such as denoising, super-resolution, and inpainting. Furthermore, the same prior can be used to invert deep neural representations to diagnose them, and to restore images based on flash-no flash input pairs.
